

Connector · explaining brief · for design partners & early operators · not a spoken script

What is happening, what Connector is, and why this demo matters

This document explains — in plain language — the problem the world is moving into, what the software is, what it does, the vision, why it matters, how a short demo should look and what it must make clear, and what a solo founder is trying to find next. It is written to be read. It is not a pitch script.

1. The problem — seven points (world we are evolving toward)

Organizations are putting language models next to real systems: money, tickets, machines, customer data, internal tools. The model can talk. The hard part is what happens when talk becomes *action* — when an agent can change the world.

1. **Agents are becoming effectors, not just chat windows.** Teams want agents that score wires, file tickets, call APIs, move money, open holds. A reply is cheap. An effect is irreversible and billable.
2. **“Stop” in the UI often does not stop spend or side effects.** Providers may keep streaming. Workers may keep hopping. The model still “wants” to finish the task. Soft cancel is not mechanical refusal.
3. **Capability is confused with authority.** Listing tools or pasting an API key looks like permission. Real permission is who may touch which address, under which policy, after which human or kernel admit.
4. **Operators cannot see live posture.** Is this agent active, ceased, quarantined, cut from egress? What world grants does it hold? Is the LLM stubbed or linked? Without one place to look, demos and audits fail.
5. **There is no reconstructible loop.** After something goes wrong, people need: what was proposed, what was admitted, what ran, what was denied, and why — not a chat scroll that mixed opinion with effect.
6. **Security theatre and lab grades get sold as production.** Soft playground modes, HMAC lab seals, and “demo ledgers” get confused with court-grade or core-banking truth. Honesty itself is part of the product.
7. **The continuum from explore → harden is missing as one spine.** Labs need soft fail. Production needs fail-closed. Most stacks fork into two products or two stories. Engineers need one runtime where posture is dialable and visible.

In one sentence: the world is evolving toward agents that can change production systems, while the industry still ships chat UX, soft cancels, and opaque tool loops — without admit-as-law, exposure meters, or reconstructible evidence.

2. What the software is

Connector is operational software for hosting *dynamic agents under engineer-chosen constraints*. It is not “another chatbot.” It is the layer where intelligence may propose, and where **Admit** (through identity, DAL, PATE, ToolDispatch) is the only path for world-changing effects.

On the hosted playground today you meet that spine as: **Workbench** (Talk → Orders → Admit), **Expometer** (live cease / quarantine / world / LLM exposure), **Action Trail** (full-page loop timeline + manage), and **SpendCease** (fence a generation so further admits refuse). The flagship story is **BankOps** — score / hold / decide / ledger on a tenant book — not a cinematic reel.

3. What it does — how it solves the problem

Problem pressure	What Connector does
Effects sneak out of chat	Ring-1 proposals never auto-dispatch; Admit is required
Stop does not stop	SpendCease fences generation, voids context tokens, reaps; next admit refuses
Opaque “what can it do?”	Expometer shows verdict, grants, LLM mode, burn / inflight
No loop history	Action Trail stitches journal + watch + activity; Orders / Evidence / Standing
Overclaiming grades	Playground honesty: tenant ledger ≠ FedWire; grade stays playground_demo
Explore vs harden fork	Same spine; posture differs — soft lab vs fail-closed harden

We guarantee **honesty and reconstructibility of consequence** — what was admitted and what ran — not absolute security, not model truth, not “we made the AI compliant.”

4. Vision

Engineers compose how dynamic and how constrained each agent is: tools, world grants, budgets, isolation tiers, HITL, cease. The same product serves a 90-minute playground tenant and a hardened node. Marketing language never outruns the control plane. Partners use Connector to put agents next to real ops — wires, tickets, machines — with admit, visibility, stop, and proof as first-class product, not afterthought.

5. Why it matters · SKIM ≈ 20 SECONDS FOR SECTIONS 1-5

If agents become default operators of software, then *who admits effects*, *who can see exposure*, *who can hard-stop spend*, and *who can prove the loop* become as important as the model. Connector exists so those questions have a runnable answer — not a slide narrative. That is why a short demo must show propose → admit → control → report on a real surface (try.cnktros.com), not a video of pretend automation.

6. The demo — how it should look, what it shows, what it must explain

· ≈ 40 SECONDS OF ATTENTION

How it should look

Dark operator UI, not a marketing landing page. One principal (BankOps) in Workbench. Expometer visible (verdict, admit line, world, LLM). Tool cards with Admit / Reject — pending, never auto-run. After Cease, a clear refuse reason (popup), Expometer flipped to ceased. Then a **dedicated** Action Trail page (URL changes to /run/trail/...) — cyan “dedicated page” framing — not a sidebar that feels like the same screen.

What the forty seconds should show (five beats)

Beat	What you see	What it explains
Whoami	BankOps identity; Expometer active	This is a governed principal, not a free chat bot
Capabilities	Tools chips; world / LLM on Expometer	Capability is listed before authority is used
Tool exec	Score \$47.5k wire → Admit → receipt / ledger	Effects only after Admit → PATE → ToolDispatch
Control	Cease → continue refuses; Expometer CEASED	Hard stop is mechanical; model desire does not matter
Report	Action Trail · Evidence focus	The loop is reconstructible for operators and partners

What the demo must not pretend

- It must not look like FedWire or court attestation.
- It must not hide that the ledger is a playground tenant store.
- It must not imply tools ran without Admit.
- It must not leave refuse as a silent disabled button — reason must be visible.

7. Solo founder — what I am trying, why it matters, paid early design partners

· ≈ 20 SECONDS OF ATTENTION

I am building Connector as a solo founder: one spine from playground to harden, with BankOps as the first honest ops story. The goal is not “more AI features.” The goal is a control plane partners can trust enough to put next to real workflows — with admit, cease, exposure, and trail as product, not slideware.

That matters because early design partners who **pay** are not buying hype. They buy time with a founder who will encode their constraints into the runtime, and they buy a surface they can critique: Workbench, Expometer, Trail, Cease. Paid early design partners fund focus. They force honesty about what is playground vs production. They turn seven industry pressures into a weekly backlog instead of a manifesto.

Ask: paid early design partners — operators or platform engineers who will run the hosted trial (or a pilot node), walk the BankOps loop, and sit with the founder on posture, grants, and proof. Not free “advisor” seats. Not logo trades. Working sessions against the live software.
